

COMP3308/COMP3608, Lecture 2

ARTIFICIAL INTELLIGENCE

Problem Solving and Search.

Uninformed Search: BFS, DFS, UCS and IDS

Informed Search: Greedy Best-First

Reference: Russell and Norvig, ch. 3

Reminders

- **Tutorials start this week**
 - **All tutorials will be on Zoom live-streamed**
 - **There are 2 on Tuesday and 14 on Wednesday**
 - **Please attend your allocated tutorial**
 - **1 tutorial will be recorded and uploaded to Canvas (under “Recorded Lectures”)**
- **All students must submit their homework in Canvas by 4pm on Tuesday (no matter when your tutorial class is)**
- **Tutorial solutions will be available on Canvas on Wednesday at 6pm (after the last tutorial)**
- **Lecture slides are posted on Saturday morning at 9am**
 - **They will not contain the answers to all questions and exercises that we do during the lecture**
 - **The complete lecture slides with the answers will be available on Monday at 12noon (after the lecture time)**

Outline

- **Problem-solving and search**
- **Search strategies**
 - **Uninformed (blind)**
 - **Informed (heuristic)**
- **Uninformed search strategies**
 - **Breadth-first**
 - **Uniform cost**
 - **Depth-first**
 - **Depth-limited**
 - **Iterative-deepening**
- **Informed search strategies**
 - **Greedy best-first**
 - **A* - next week**

Problem Solving and Search

Solving Problems by Searching

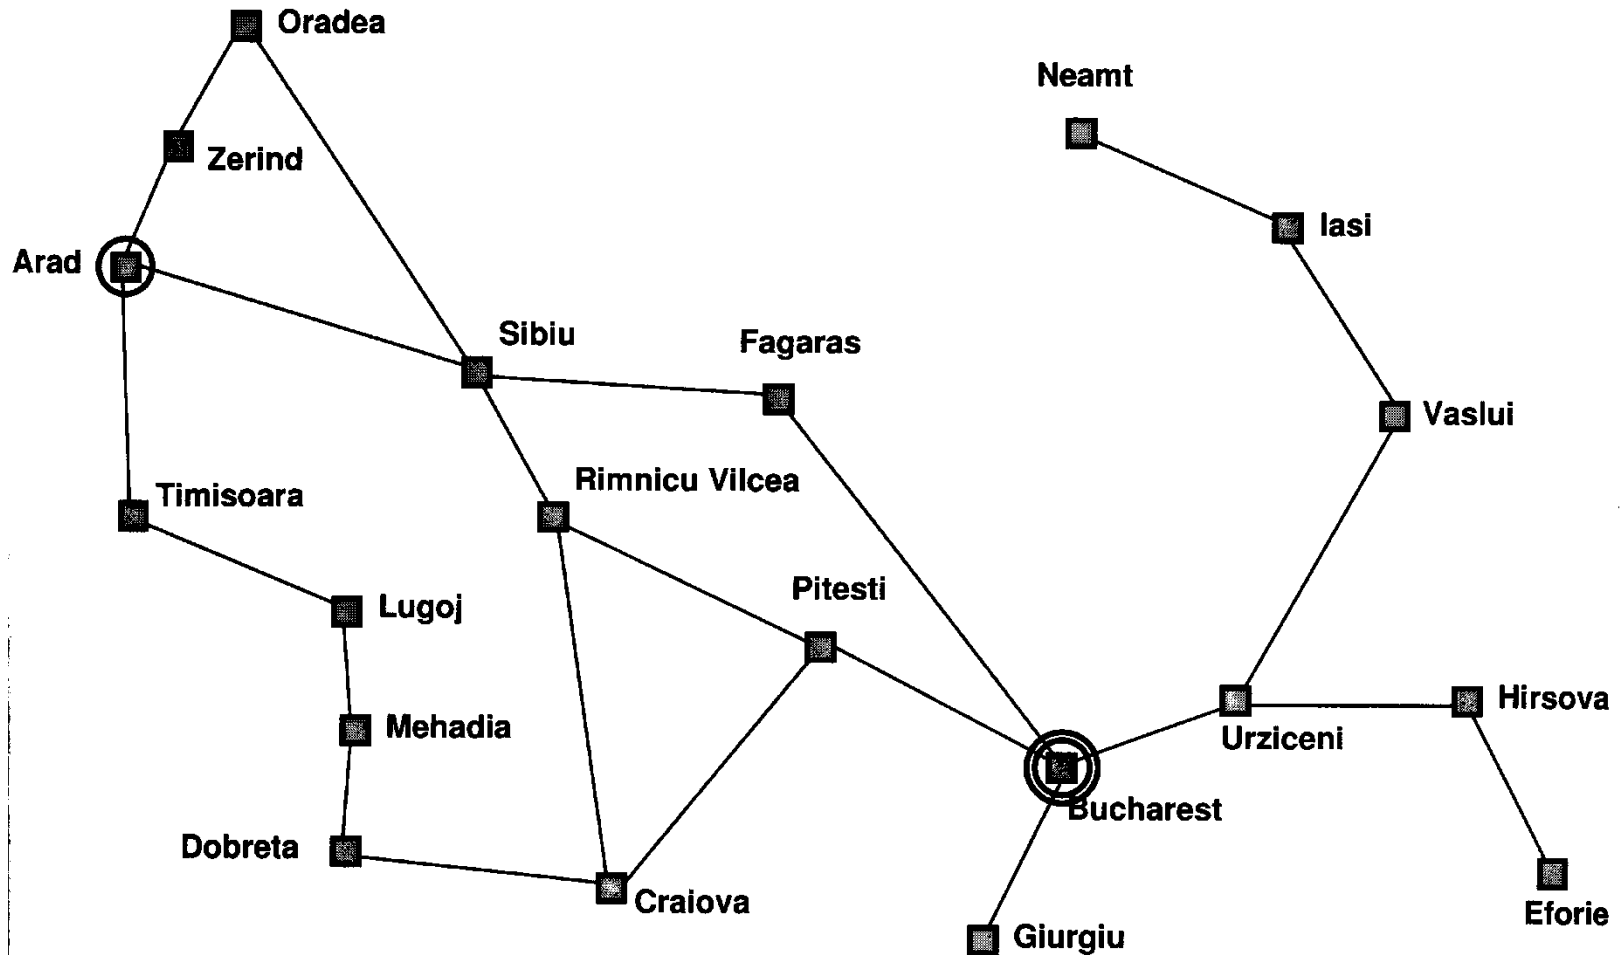

- Many tasks can be formulated as search problems
- **Task:** to get from an *initial problem state* to a *goal state*
 - Driving: starting address -> destination address
 - Chess: initial board position -> checkmate position
 - Reasoning: set of facts and rules + query -> answer
- **Solution:** a path from the initial state to the goal state
- Operators
 - possible actions, possible moves in a game
- Cost (quality) of operators
 - distance, time, money
 - strength of board position in games

Example: Romania

- **On holiday in Romania**
 - currently in Arad
 - flight leaves tomorrow from Bucharest
- **Step 1. Formulate *goal*: be in Bucharest**
- **Step 2. Formulate search problem:**
 - *states*: various cities
 - *operators*: drive between cities, e.g. from Arad to Sibiu, from Arad to Zerind
- **Step 3. Find solution (path):**
 - a sequence of cities from Arad to Bucharest, e.g. Arad, Sibiu, Fagaras, Bucharest

Romania Example - Map

Romania

http://en.wikipedia.org/wiki/File:Location_Romania_EU_Europe.PNG

Search Problem Formulation

- A search problem is defined by 4 items
 - 1) **Initial state**, e.g. Arad
 - 2) **Goal state** (1 or more)
 - Stated **explicitly**, e.g. Bucharest
 - Stated **implicitly** with a goal test, e.g. checkmate state
 - 3) **Operators** = actions
 - A set of possible actions transforming 1 state to another , e.g. Arad->Zerind, Arad->Sibiu, etc.
 - 4) **Path cost function** – assigns a numeric value to each path
 - Reflects the performance measure
 - E.g. time, path length in km, number of operators executed
- **Solution** – a path from the initial to a goal state
 - Its quality is measured by the path cost
 - Optimal solution is the one with the lowest path cost
- **State space** - all states reachable from the initial state by operators

Choosing States and Actions - Abstraction

- **Real problems are too complex**, to solve them we need to *abstract* them, i.e. to simplify them by removing the unnecessary details
 - E.g. we ignore the weather, travel companion, scenery; they are **irrelevant** for the task of finding a path to Bucharest
 - The **actions need to be suitably specified**, e.g. “turn the steering wheel to the left by 5 degrees” is not appropriate
 - => the *level of abstraction* must be appropriate (valid and useful)
- (Abstract) state = set of real states
- (Abstract) action = complex combination of real actions
- (Abstract) solution = a real path that is solution in the real world

Example Problem 1: The 8-puzzle

7	2	4
5		6
8	3	1

Start State

	1	2
3	4	5
6	7	8

Goal State

a sliding block puzzle

- *States?* 1 state = 1 board configuration of the tiles
- *Operators?* Move blank left, right, up, down
- *Goal state?* Given
- *Path cost?* 1 per move, i.e. path cost=length of path=number of steps

Example Problem 2: The 8-queens

- Place 8 queens on a chessboard (8x8) so that no queen attacks each other
- Is this a solution?

- *Goal state?* 8 queens on board, none attacked
- *Path cost?* 0 (= only the goal state matters and not the number of steps). Other options are also possible, e.g. 1 per move.
- *States =?* 1 state = 1 board configuration of the tiles
- *Operators =?* Put 1 queen on the board or move 1 queen

8-queens - Different Types of Problem Formulation

1. **Incremental** – start with an empty board, add 1 queen at a time
2. **Complete-state** – start with all 8 queens and move them around

Let's take a closer look at 2 possible incremental formulations!

8-queens – Incremental Formulation 1

- *States?* Any arrangement of 0 to 8 queens
 - *Initial state?* No queens on the board
 - *Operators?* Add a queen to any square
 - State space = **1.8×10^{14} states (= $64 \times 63 \times \dots \times 57$)**
- 
- Can you suggest a better formulation?
 - Prohibit placing a queen in any square that is already attacked!

8-queens – Incremental Formulation 2

- *States?* Any arrangement of 0 to 8 queens, 1 in each column, with no queen attacking another
- *Initial state?* No queens on the board
- *Operators?* Place a queen in the left-most empty column such that it is not attacked by any other queen
- State space: 2057 states (has been proven)
- For 100-queens:
 - formulation 1: 10^{400} states
 - formulation 2: 10^{52} states (huge improvement but problem still not tractable)
- The problem formulation is very important!

Searching for Solutions

- How can we solve the 8-queens puzzle or the Romania example?
- By *searching the state space*
- We can generate a *search tree* starting from the **initial state** and applying the **operators**
- Or we can generate a *search graph* – in a graph the **same state** can be reached from **multiple paths**

Tree-Search algorithm – Pseudo Code

- **Basic idea:** offline exploration of the state space by generating successors of the explored states (i.e. by *expanding* states)

```
function TREE-SEARCH(problem, strategy) returns a solution, or failure
  initialize the search tree using the initial state of problem
  loop do
    if there are no candidates for expansion then return failure
    choose a leaf node for expansion according to strategy
    if the node contains a goal state then return the corresponding solution
    else expand the node and add the resulting nodes to the search tree
```

Annotations in the pseudo-code:

- start with the initial node* (points to "initial state of *problem*")
- the initial node at the beginning* (points to "leaf node")

1. **Choose a node for expansion** based on the search strategy
2. **Check if it is a goal node**
Yes-> return solution
No -> expand it by generating its children

Expanded and Fringe Lists

- We will keep two lists:
 - **Expanded** – for nodes that **have been expanded**
 - **Fringe** – for nodes that have been **generated but not expanded yet.**
 - We will keep the **fringe ordered (implemented as a priority queue)** and always select for expansion the first node of the fringe
- For the figure:
 - **Expanded:** Arad
 - **Fringe:** Sibiu, Timisoara, Zerind
 - All the other nodes have not been generated yet
 - Note the notation in the figure for the different types of nodes

Tree Search Example

- Let's put the children of the expanded node at the end of the fringe

Fringe: Arad

Is Arad a goal node? No => expand it

Expanded: none

Tree Search Example (2)

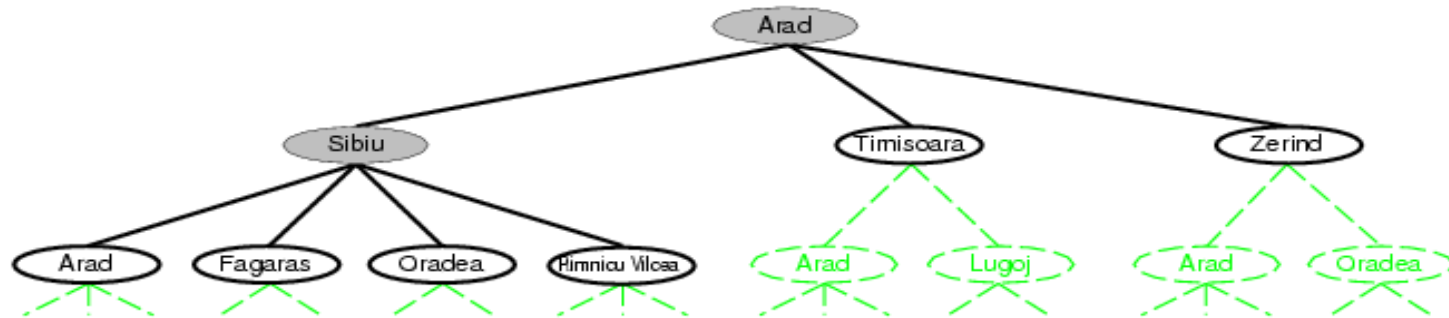

Fringe: Sibiu, Timisoara, Zerind

Expanded: Arad

Is Sibiu a goal node?

No => expand it

Tree Search Example (3)

Fringe: Timisoara, Zerind, Arad, Fagaras, Oradea, Rimnicu Vilcea

Expanded: Arad, Sibiu

Tree Search – More Detailed Pseudo Code

```
function TREE-SEARCH(problem, fringe) returns a solution, or failure
  fringe ← INSERT(MAKE-NODE(INITIAL-STATE[problem]), fringe)
  loop do // nodes in fringe ordered based on their priority according to the search strategy
    if fringe is empty then return failure
    node ← REMOVE-FRONT(fringe) //select node for expansion, then check if it is a goal
    if GOAL-TEST[problem](STATE[node]) then return SOLUTION(node)
    fringe ← INSERTALL(EXPAND(node, problem), fringe)
```

```
function EXPAND(node, problem) returns a set of nodes
  successors ← the empty set
  for each action, result in SUCCESSOR-FN[problem](STATE[node]) do
    s ← a new NODE
    PARENT-NODE[s] ← node; ACTION[s] ← action; STATE[s] ← result
    PATH-COST[s] ← PATH-COST[node] + STEP-COST(node, action, s)
    DEPTH[s] ← DEPTH[node] + 1
    add s to successors
  return successors
```

Is the first node in the fringe a goal node?

Yes => stop and return solution

No => expand it:

- Move it to the expanded list
- Generate its children and put them in the

fringe in a order defined by the search strategy
(top of the fringe = most desirable child)

- We will keep the fringe ordered

Nodes vs States

- A *node* is **different** than a *state*
- A node:
 - **represents a state**
 - is a **data structure** used in the search tree
 - includes *parent, children*, and other relevant information e.g. *depth* and *path cost g*

Search Strategies

- A search strategy defines which node from the fringe is most promising and should be expanded next
- We will keep the nodes in the fringe ordered based on the search strategy and always expand the first one (i.e. the best one)
- Evaluation criteria
 - *Completeness* – is it guaranteed to find a solution if one exists?
 - *Optimality* – is it guaranteed to find an *optimal (least cost path)* solution?
 - *Time complexity* – how long does it take to find the solution? (measured as number of generated nodes)
 - *Space complexity* – What is the maximum number of nodes in memory?
- Time and space complexity are measured in terms of:
 - b – max branching factor of the search tree (we can assume that it is finite)
 - d – depth of the optimal (least cost) solution
 - m – maximum depth of the state space (can be finite or not finite, i.e. ∞)
- Two types of search methods: *uniformed (blind)* and *informed (heuristic)*

Uninformed (Blind) Search Strategies

Uninformed (Blind) Search Strategies

- Uninformed strategies:
 - Do not use **problem-specific heuristic knowledge**
 - **Generate children in a systematic** way, e.g. level by level, from left to right
 - Know if a child node is a goal or non-goal node
 - **Do not know if one non-goal child is better (more promising) than another one.** Exception: UCS, but this is not based on heuristic knowledge.
 - In contrast, informed (heuristic) use heuristic knowledge to determine the most promising non-goal child
- 5 uninformed search strategies
 - Breadth-first
 - Uniform-cost
 - Depth-first
 - Depth-limited
 - Iterative deepening

Breadth-First Search (BFS)

- **Expands the shallowest unexpanded node**
- **Implementation: insert children at the **end of the fringe****

Fringe: A

Expanded: none

Is the first node in the fringe a goal node?

Yes => stop and return solution

No => expand it:

- Move it to the expanded list
- Generate its children and put them in the fringe in a order defined by the search strategy

Goal node

Breadth-First Search (BFS)

- Expands the shallowest unexpanded node
- Implementation: insert children at the end of the fringe

Fringe: B, C

Expanded: A

Breadth-First Search (BFS)

- Expands the shallowest unexpanded node
- Implementation: insert children at the end of the fringe

Fringe: C, D, E

Expanded: A, B

Breadth-First Search (BFS)

- Expands the shallowest unexpanded node
- Implementation: insert children at the end of the fringe

Fringe: D, E, F, G

Expanded: A, B, C

Breadth-First Search (BFS)

- Expands shallowest unexpanded node
- Implementation: insert children at the end of the fringe

Fringe: E, F, G

Expanded: A, B, C, D

Fringe: F, G

Expanded: A, B, C, D, E

Fringe: G

Expanded: A, B, C, D, E, F

G is a goal node => stop

Order of expansion: ABCDEFG (the goal node is also included)

Goal node found: G

Solution path found: ACG (requires tracing back)

BFS for Romania Example

- **There will be loops (repeated states)**
- **Needs a repeated state checking mechanism**

Properties of BFS

- **Complete?** Yes (if branching factor b is finite but we assume this)
- **Optimal?**
 - **Optimal solution = least cost path**
 - **It doesn't consider the step cost + we need to know the step costs**
 - **If all step costs are the same, e.g. =1, is BFS optimal? Yes**
 - **If the step costs are different, is BFS optimal? No**

The shallowest goal node is not necessarily the optimal one!

Suppose C and J were goal nodes and J is a better solution than C; BFS will find C – not optimal

Properties of BFS (2)

- Complete? Yes
- Optimal? Not optimal in general; Yes, if step cost is the same, e.g. =1
- Time? generated nodes = $1+b+b^2+b^3+b^4 + \dots + b^d = O(b^d)$, exponential
- Space? $O(b^d)$ (keeps every node in memory)
- Both time and space are problems as they grow exponentially with depth but space is the bigger problem!

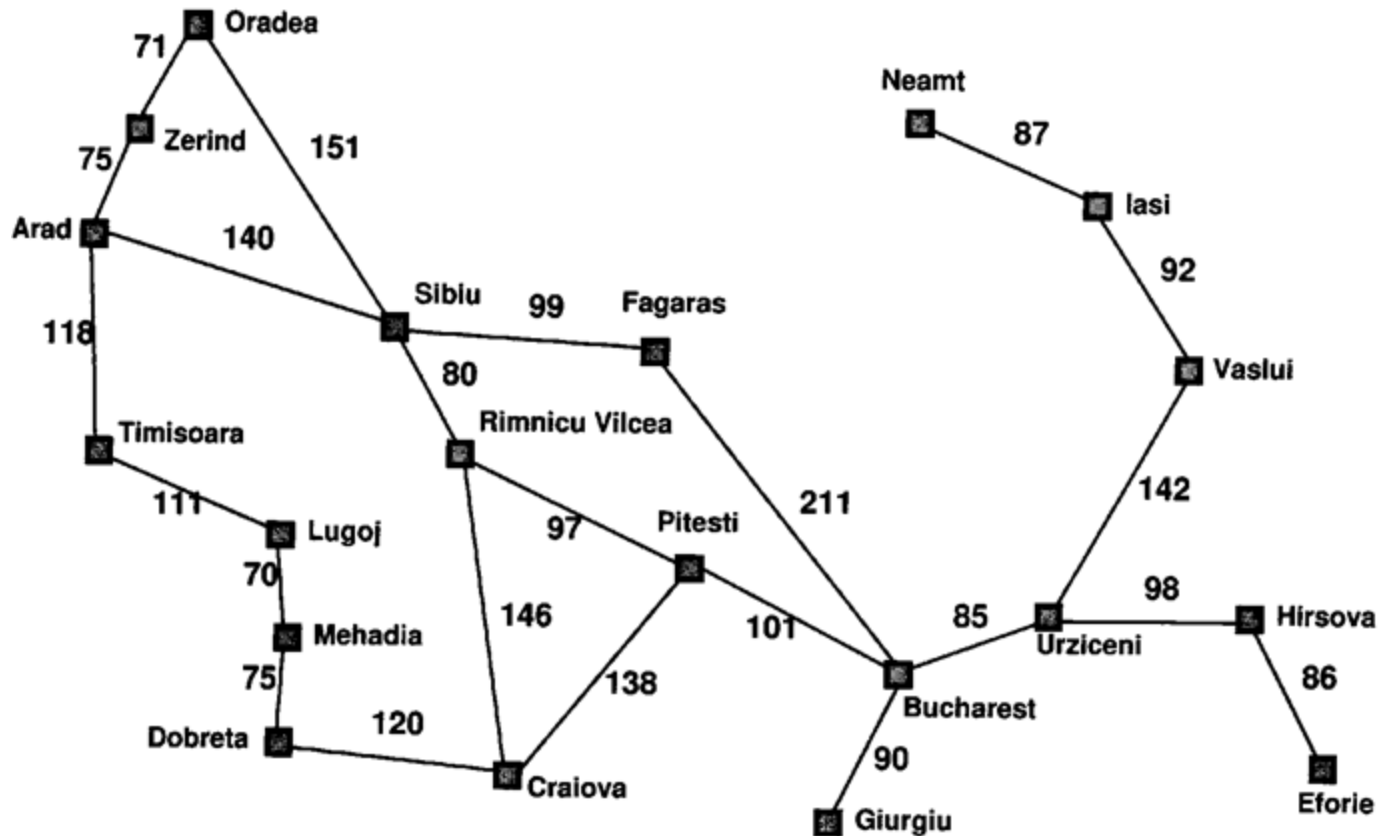

Depth	Nodes	Time	Memory
2	110	.11 milliseconds	107 kilobytes
4	11,110	11 milliseconds	10.6 megabytes
6	10^6	1.1 seconds	1 gigabyte
8	10^8	2 minutes	103 gigabytes
10	10^{10}	3 hours	10 terabytes
12	10^{12}	13 days	1 petabyte
14	10^{14}	3.5 years	99 petabytes
16	10^{16}	350 years	10 exabytes

Figure 3.13 Time and memory requirements for breadth-first search. The numbers shown assume branching factor $b = 10$; 1 million nodes/second; 1000 bytes/node.

Search problems with exponential complexity can NOT be solved by uninformed search except for small depth & small branching factor.

We may wait 13 days for the solution to an important problem but there is still no personal computer with 1 petabyte of memory!

Romania with Step Coast in km

Uniform Cost Search (UCS)

- We saw that:
 - BFS does not consider the step cost at all; it simply systematically expands the nodes level by level, from left to right
 - **BFS finds the shallowest goal node but this may not be always the optimal solution** (least cost solution = shortest path)
- **UCS considers the step cost.** It expands the least-cost unexpanded node - the node n with the *lowest path cost $g(n)$ from the initial state*
- Implementation: insert nodes in the fringe **in order of increasing path cost from the root**

UCS for the Romania Example (1)

Fringe: Arad

Expanded: none

Is Arad a goal state? No

-Move it to Expanded

**-Generate its children and
put them in Fringe in
order**

fringe

UCS for the Romania Example

Fringe: (Zerind,75), (Timisoara, 118), (Sibiu, 140)

Expanded: Arad

The fringe is ordered based on the path cost from the root

UCS for the Romania Example

Fringe: (Timisoara, 118), (Sibiu, 140), (Oradea,146), (Arad, 150)

Expanded: Arad, (Zerind, 75)

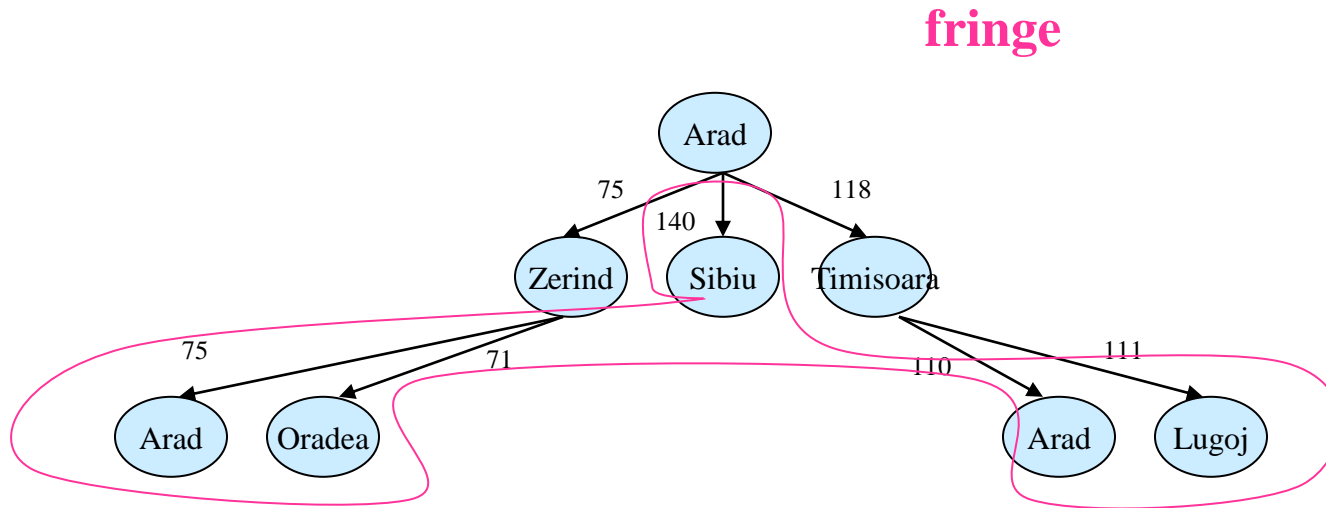

The fringe is ordered based on the path cost from the root

UCS for the Romania Example

Fringe: (Sibiu, 140), (Oradea,146), (Arad, 150), (Arad,228), (Lugoj, 229)

Expanded: Arad, (Zerind, 75), (Timisoara, 118)

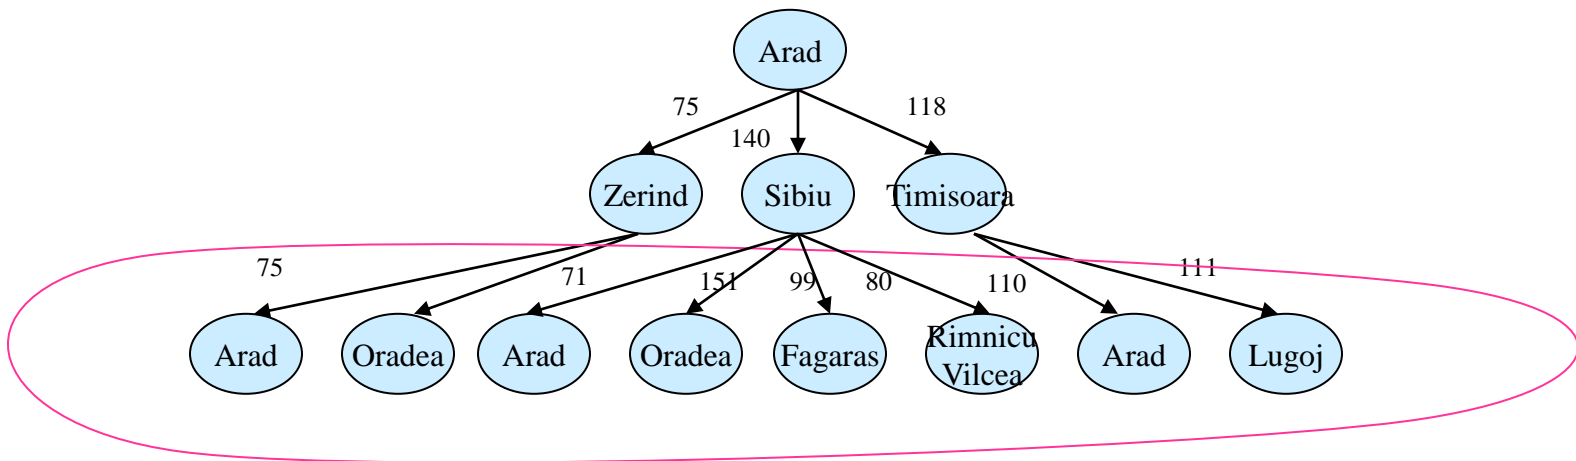

The fringe is ordered based on the path cost from the root

UCS for the Romania Example

Fringe: (Oradea,146), (Arad, 150), (Rimnicu Vilcea, 220),
(Arad,228), (Lugoj, 229), (Fagaras, 239), (Oradea , 291)

Expanded: Arad, (Zerind, 75), (Timisoara, 118), (Sibiu, 140)

fringe

The fringe is ordered based on the path cost from the root

etc. – not finished

Properties of UCS

- Complete? Yes (if step cost > 0)
 - Optimal? Yes
 - Time? Depend on path costs not depths => difficult
 - Space? to characterize them in terms of b and d
-
- Time? $O(b^{1+\lceil C^*/\epsilon \rceil})$, typically $> O(b^d)$ -> because UCS may explore long paths of small steps before exploring paths with large steps which might be more useful
 - Space? $O(b^{1+\lceil C^*/\epsilon \rceil})$
 - C^* - cost of optimal solution
 - ϵ - the smallest step cost

UCS and BFS

- When is UCS equivalent to BFS? What should be the step cost and the $g(n)$ cost? Assume that among the nodes with the same priority the left most is expanded first. Reminder:
 - $g(n)$ is the cost from the root node to a given node
 - step cost is the cost between 2 nodes

Answer – in all of these cases:

1. step cost is 1
2. step cost is the same (a constant) - generalization of case 1
3. $g(n) = \text{depth}(n)$
4. $g(n)$ is the same at each level and increasing as the level increases, e.g. 5 for level 1, 7 for level 2, etc.

- Draw a tree for each of these cases and run UCS and BFS!

Depth-First Search (DFS)

- Expands the **deepest** unexpanded node
- Implementation: insert children at the front of the fringe

Fringe: A

Expanded: none

Goal node: M

Depth-First Search (DFS)

- Expands the deepest unexpanded node
- Implementation: insert successors at the front of the fringe

Fringe: B, C

Expanded: A

Depth-First Search (DFS)

- Expands the deepest unexpanded node
- Implementation: insert successors at the front of the fringe

Fringe: D, E, C

Expanded: A, B

Depth-First Search (DFS)

- Expands the deepest unexpanded node
- Implementation: insert successors at the front of the fringe

Fringe: H, I, E, C

Expanded: A, B, D

Depth-First Search (DFS)

- Expands the deepest unexpanded node
- Implementation: insert successors at the front of the fringe

Fringe: I, E, C

Expanded: A, B, D, H

Depth-First Search (DFS)

- Expands the deepest unexpanded node
- Implementation: insert successors at the front of the fringe

Fringe: E, C

Expanded: A, B, D, H, I

Depth-First Search (DFS)

- Expands the deepest unexpanded node
- Implementation: insert successors at the front of the fringe

Fringe: J, K, C

Expanded: A, B, D, H, I, E

Depth-First Search (DFS)

- Expands the deepest unexpanded node
- Implementation: insert successors at the front of the fringe

Fringe: K, C

Expanded: A, B, D, H, I, E, J

Depth-First Search (DFS)

- Expands the deepest unexpanded node
- Implementation: insert successors at the front of the fringe

Fringe: C

Expanded: A, B, D, H, I, E, J, K

Depth-First Search (DFS)

- Expands the deepest unexpanded node
- Implementation: insert successors at the front of the fringe

Fringe: F, G

Expanded: A, B, D, H, I, E, J, K, C

Depth-First Search (DFS)

- Expands the deepest unexpanded node
- Implementation: insert successors at the front of the fringe

Fringe: L, M, G

Expanded: A, B, D, H, I, E, J, K, C, F

Depth-First Search (DFS)

- **Expands the deepest unexpanded node**
- **Implementation: insert successors at the front of the fringe**

Fringe: M, G

Expanded: A, B, D, H, I, E, J, K, C, F, L

Depth-First Search (DFS)

- Expands the deepest unexpanded node
- Implementation: insert children at the front of the fringe

Fringe: M, G

Expanded: A, B, D, H, I, E, J, K, C, F, L

M is a goal node => stop

order of expansion: **ABDHIEJKCF**LM

solution node found: **M**

solution path found: **ACFM**

DFS for Romania Example

- DFS can perform infinite cyclic explorations => **needs a finite, non-cyclic search space** or a repeated state checking mechanism

Properties of DFS

- Complete?
 - **No**, fails in infinite-depth spaces (i.e. $m = \infty$)
 - Yes, in finite spaces (i.e. if m is finite)
- Optimal? **No**
 - May find a solution longer than the optimal (even if step cost=1)
- Time? $1+b+b^2+b^3+b^4 + \dots + b^m = O(b^m)$ similar to BFS
 - higher than BFS as $m \gg d$ (m =max depth, d =least cost solution depth)
- Space? $O(bm)$, linear; excellent; Why?

Can get stuck going down a very long (or even infinite) path e.g. suppose the left subtree was unbounded and did not contain a goal node – DFS would never terminate

Suppose J and C were goal nodes and C is a better solution than J; DFS will find J – not optimal

Space Complexity of DFS

- Space? $O(bm)$, linear; excellent – why?
- Once a node has been expanded, it can be removed from memory as soon as all its descendants have been fully explored

Depth-Limited Search

- Depth-limited search = DFS with depth limit l
 - i.e. it imposes a cutoff on the maximum depth
- Properties – similar to DFS:
 - Complete? Yes (as the search depth is always finite)
 - Optimal? No
 - Time? $1 + b^2 + b^3 + b^4 + \dots + b^l = O(b^l)$
 - Space? $O(bl)$
- Problem - how to select a good limit l ? Based on domain knowledge.
 - There are 20 cities on the map of Romania => if there is a solution it must be of length 19 at most => $l=19$
 - We can even see that any city can be reached from any other city in at most 9 steps; this is called *diameter of a state space* => $l=9$
 - However, for most problems the diameter of the state space is not known in advance , i.e. before we have solved the problem

Iterative Deepening Search (IDS)

- Sidesteps the issue of choosing the best depth limit by **trying all possible depth limits** in turn (0, 1, 2, etc.) and applying DFS
- for depth=0 to ∞ do *depth-limited search(depth)*:

```
function ITERATIVE-DEEPENING-SEARCH(problem) returns a solution, or fail-  
ure  
  inputs: problem, a problem  
  for depth  $\leftarrow$  0 to  $\infty$  do  
    result  $\leftarrow$  DEPTH-LIMITED-SEARCH(problem, depth)  
    if result  $\neq$  cutoff then return result
```

- Tries to combine the benefits of DFS (low memory) and BFS (completeness if b is finite and optimality if step costs are the same) by **repeated DFS searches with increased depth**
- The nodes **close to the root** will be **expanded multiple times** but the **number of these nodes is small** – the majority of the nodes are close to the leaves, not the root \Rightarrow the overhead is small

IDS, $l=0$

cutoff limit $l=0$

A tree till level $l=0$; do DFS

Goal found?

Yes \rightarrow stop

No \rightarrow increment l and repeat

Limit = 0

Expanded: A

The tree we are searching –
M is the goal node

IDS, $l=1$

cutoff limit $l=1$

A tree till level $l=1$; do DFS

Goal found?

Yes \rightarrow stop

No \rightarrow increment l and repeat

Limit = 1

Expanded: A, B, C

IDS, l=2

Limit = 2

Expanded: A, B, D, E, C, F, G

IDS, l=3

Limit = 3

Expanded: A, B, D, H, I, E, J, K, C, F, L, M (goal)

IDS – Overhead of Multiple Expansion

- May seem wasteful as many nodes are expanded multiple times
- But **for most problems the overhead of this multiple expansion is small!**
 - BFS: # expansions: $1+b+b^2+\dots+b^d$, i.e. 111 111 for $b=10$, $d=5$
 - IDS: #expansions: $(d+1)1+(d)b+(d-1)b^2+\dots+3b^{d-2}+2b^{d-1}+1b^d$, i.e. 123 456 for $b=10$, $d=5 \Rightarrow$ only 11% more
- IDS is the preferred method when there is a large search space and the depth of the solution is unknown

Expanded:

A

A, B, C

A, B, D, E, C, F, G

A, B, D, H, I, E, J, K, C, F, L, M (goal)

Properties of IDS

b – branching factor
 d - depth of least cost solution
 m – max depth

- Combines the benefits of DFS and BFS
- Complete? As BFS:
Yes [DFS: yes, if m is finite; no otherwise]*
- Optimal? As BFS:
No in general; Yes if step cost=1 [DFS: not optimal, even if step cost=1] *
- Time? As BFS:
 $(d+1)b^0 + db^1 + (d-1)b^2 + \dots + b^d = \mathbf{O(b^d)}$ [DFS: $O(b^m)$] *
- Space? As DFS:
 $O(bd)$, linear
- Where are the **improvements of IDS in comparison to DFS?**
 - in **completeness, optimality and time** (shown with *)
- Can be modified to explore uniform-cost tree

Summary

Example

- **G is the goal.**
Give the list of expanded nodes and the solution path.

- **DFS?**
 - SADEG, solution found: SAG (non optimal)
- **BFS?**
 - SABCDEG, solution found: SAG (non-optimal solution; will find optimal solution only if step cost=1)
- **UCS?**
 - **Resolving ties: Among nodes with the same priority, expand the node that was added first to the fringe**
 - SADBCEG, solution found: SBG (optimal)
Among nodes with the same priority (E and C, g=8), the first added to the fringe (C) was chosen to be expanded first
- **IDS (l=2)**
 - S SABC SADEG, solution found: SAG (non-optimal solution; will find optimal solution only if step cost=1)

Real-World Path Finding Problems

- **Planning trips from A to B - Google maps, planning public transport trips**
 - **Example - web sites for planning air travel:**
 - **Initial and goal states:** specified by the user
 - **Actions:** take any flight from the initial location, leaving after the current time with enough time for within-airport transfer
 - **Path cost:** monetary cost, flight time, waiting time, time of the day (too early/too late), frequent-flyer millage awards, customs and immigration procedures
- **VLSI layout - position millions of components and connections on a very small chip (to minimize area and circuits delays)**
- **Assembling objects by a robot - find the correct order for the parts; wrong order will require undoing some of the work already done**
- **Protein design - find a sequence of amino acids that will fold into a 3-dimensional protein with useful properties (i.e. curing a disease)**

Informed (Heuristic) Search Strategies

Informed vs Uninformed Search

- A search strategy defines the order of node expansion
- *Uninformed search* strategies **do not use problem specific knowledge** beyond the definition of the problem, i.e. they **do not use heuristic knowledge**. They:
 - expand nodes **systematically**, e.g. BFS: level by level, from left to right
 - know if a given node is a goal or non-goal node
 - cannot compare 2 non-goal nodes – they do not know if one non-goal node is better than another one based on heuristic knowledge
 - UCS does this but it is not based on heuristic knowledge but path cost so far, so it is classified as uninformed
 - are typically inefficient in finding the solution (time and space)
- *Informed search* strategies use problem-specific **heuristic** knowledge to select the order of node expansion. They:
 - **can compare non-goal nodes – they know if one non-goal node is better than another one**
 - are typically more efficient

Best-first Search

- How can informed strategies compare non-goal nodes?
- By using domain specific knowledge to devise an *evaluation function* which estimates how good each node is
- The evaluation function assigns a *value* to each node
- At each step, **the best node is expanded (the one with the best value)**
- This is called *best-first search*
 - Note that we don't *really* know which is the best node as we **use an estimate based on the evaluation function**. So best-first search expands the node that *appears* to be the best.
- Fringe: insert children in decreasing order of desirability
- We will study 2 **best-first** search algorithms: *greedy* and A^*

Greedy Search

Romania with Step Coast and Straight-line Distance to Bucharest

Greedy Search (GS)

- It uses the so called h value as an evaluation function (h from *heuristic*)
- The $h(n)$ for a node n is the estimated cost from n to a goal node
- E.g. for the Romania example we can use $h(n) = SLD(n, Bucharest) =$ straight-line distance from n to Bucharest
- Note that the h value of a goal node is 0, i.e. $h(goal) = 0$
- GS expands the node with the smallest h , i.e.
 - The node that appears to be closest to a goal
- Thus: GS minimizes h , the estimated cost to a goal

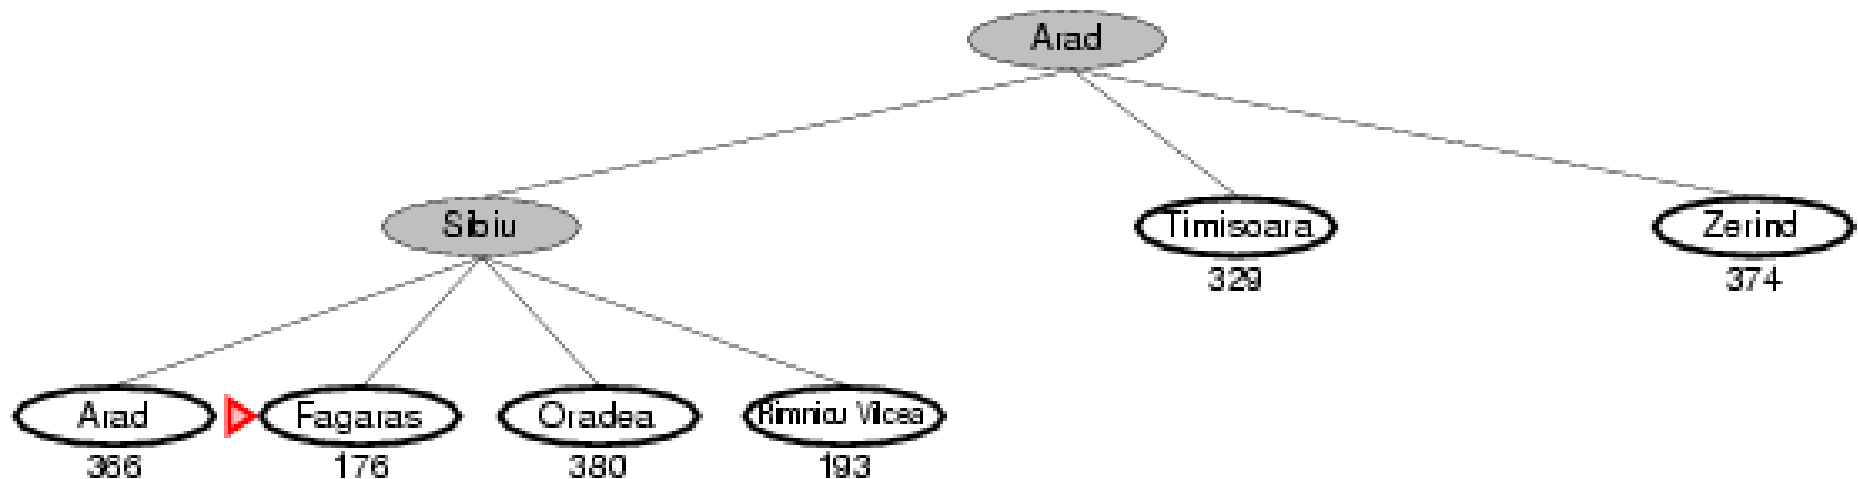

Greedy Search for Romania Example

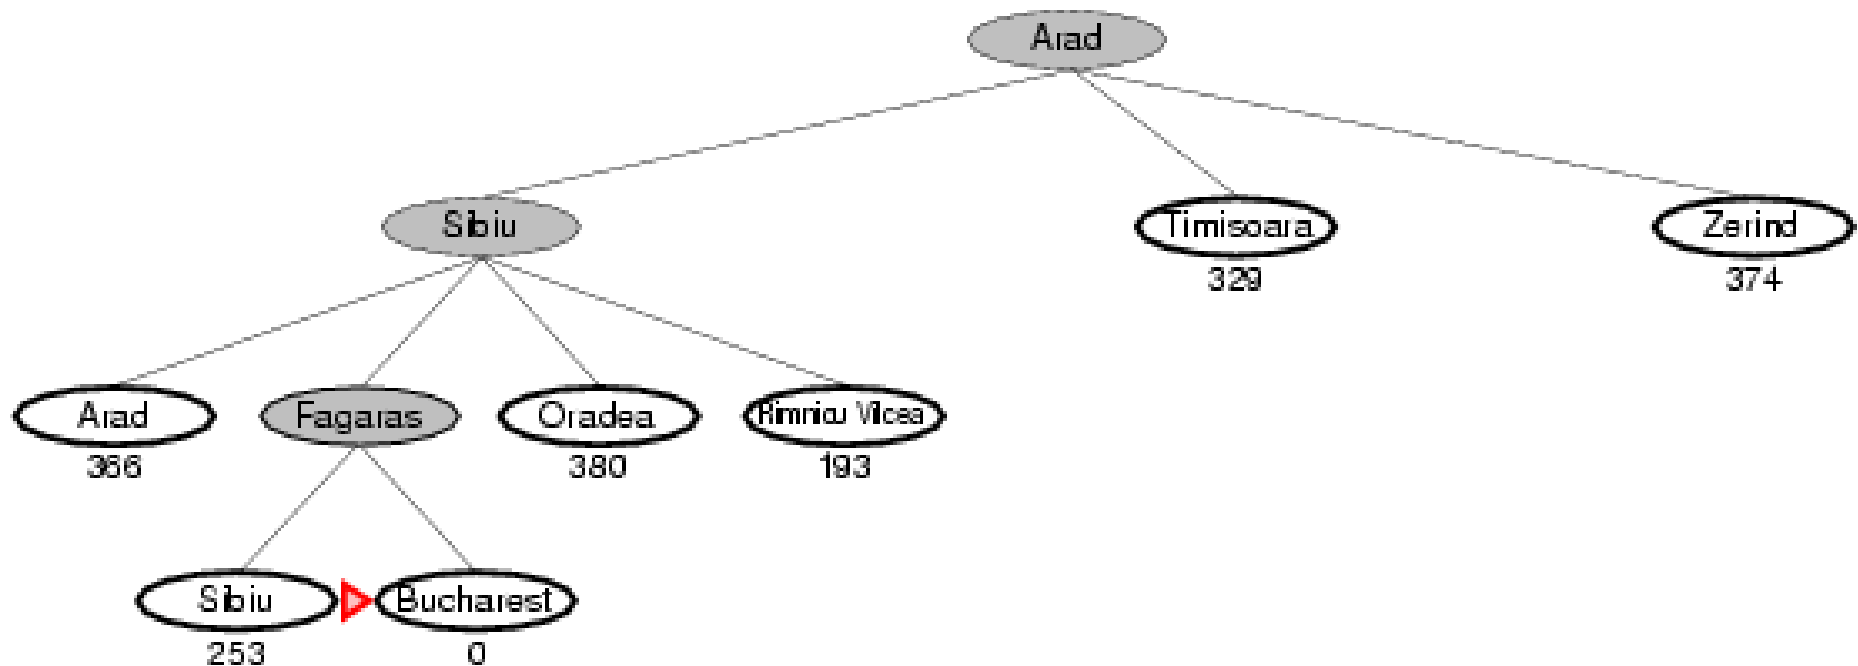

Greedy Search for Romania Example

Greedy Search for Romania Example

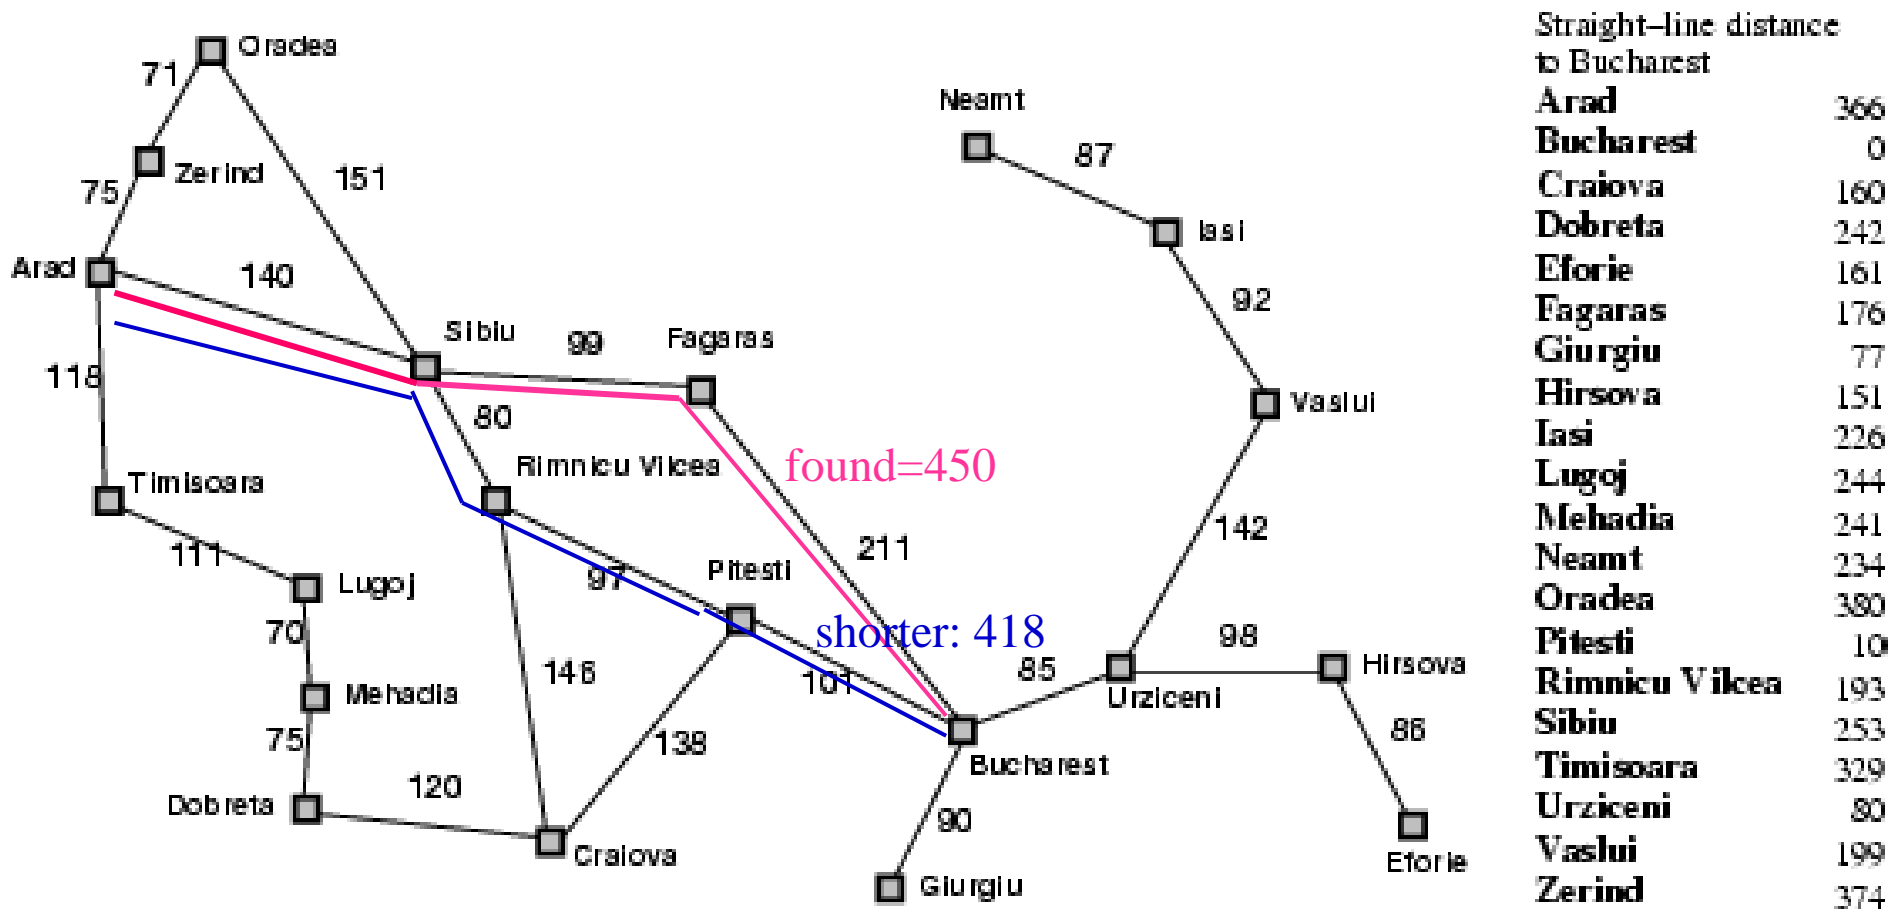

Greedy Search for Romania Example

Solution path: Arad-Sibiu-Fagaras-Bucharest, cost=450

Optimal =?

Greedy Search for Romania Example

Solution path: Arad-Sibiu-Fagaras-Bucharest, cost=450

Optimal =?

Greedy Search – Another Example

- **Given:**
 - **Goal nodes: C, I, E and K**
 - **Step path cost: along the links**
 - **h value of each node: in ()**
- **Run GS**
 - **List of expanded nodes =?**
 - **Solution path =? Cost of the solution path=?**

Solution

- **Fringe:** S
- **Expanded:** nil

Solution

- **Fringe:** (A,3), (B,4)
- **Expanded:** S

Solution

- **Fringe:** (C,0), (B,4), (D, 5) //C and D are added and the fringe is ordered
- **Expanded:** S, (A,3)

Solution

- **C is selected for expanding; is it a goal node? Yes ->stop**
- **Expanded: S, A, C //note that the goal node is also considered to be
// expanded and is included in the list of expanded**
- **Solution path: SAC, path cost: $2+8=10$**

Solution

- Is SAC the optimal solution (i.e. shortest path to a goal)?

Properties of Greedy Search

- **Complete?** As DFS
 - Yes, in finite space (if m is finite)
 - No – **fails in infinite spaces** (and can get stuck in loops, e.g. Iasi->Neamt->Iasi->Neamt)
- **Optimal?** **No** (e.g. Arad->Sibiu->R.Vincea->Pitesti->Buharest is shorter)
- **Time?** $O(b^m)$, but a **good heuristic can give dramatic improvement**
- **Space?** $O(b^m)$, keeps every node in memory

Question

- $g(n)$ = cost so far
- $h(n)$ = estimated cost to the goal
- Greedy search uses $h(n)$

Suppose that we run a greedy search algorithm with $h(n) = g(n)$. This greedy search will be equivalent to what kind of uninformed search?

In other words, which algorithm uses $g(n)$?

UCS
